- Midterm
- Final Project

#### THIS WEEK: DISTRIBUTED COORDINATION

- Distributed Locking
- Consensus
- Elections
- State Machine Replication
- Blockchain

# MHA FOCKS

- Locks let us protect a shared resource
  - A database, values in shared memory, files on a shared file system, throttle control on a drone, etc
- How to manage a lock in a distributed environment?
- How do locks limit scalability?

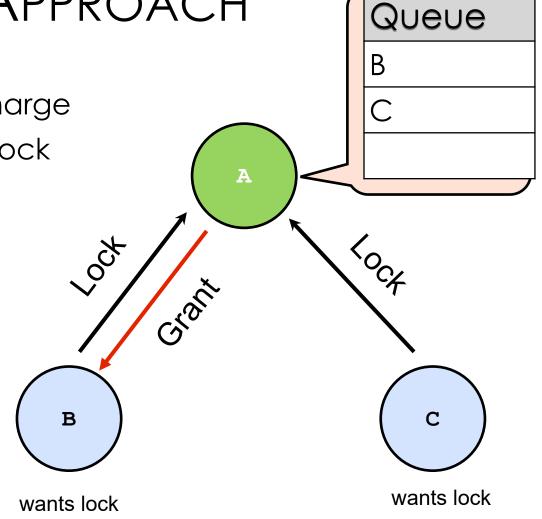

• Simplest approach: put one node in charge

• Other nodes ask coordinator for each lock

• Block until they are granted the lock

Send release message when done

- Coordinator can decide what order to grant lock
- Do we get:
  - Mutual exclusion?
  - Progress?
  - Resilience to failures?
  - Balanced load?

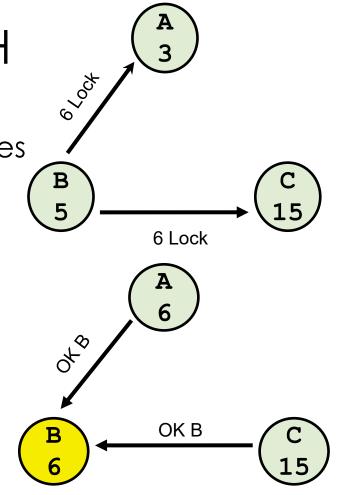

Lock

# DISTRIBUTED APPROACH

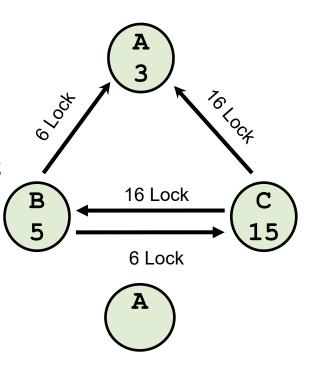

Use Lamport Clocks to order lock requests across nodes

- Send Lock message with ++clock
  - Wait for OKs from all nodes
- When receiving Lock msg:
  - Update clock following Lamport's rules
  - Send OK if not interested
  - If I want the lock:
    - Send OK if request's clock is smaller than own
    - Else, put request in queue
- When done with a lock:
  - Send OK to anybody in queue

# DISTRIBUTED APPROACH

- Use Lamport Clocks to order lock requests across nodes
- Send Lock message with ++clock
  - Wait for OKs from all nodes
- When receiving Lock msg:
  - Update clock following Lamport's rules
  - Send OK if not interested
  - If I want the lock:
    - Send OK if request's clock is smaller than own
    - Else, put request in queue
- When done with a lock:
  - Send OK to anybody in queue

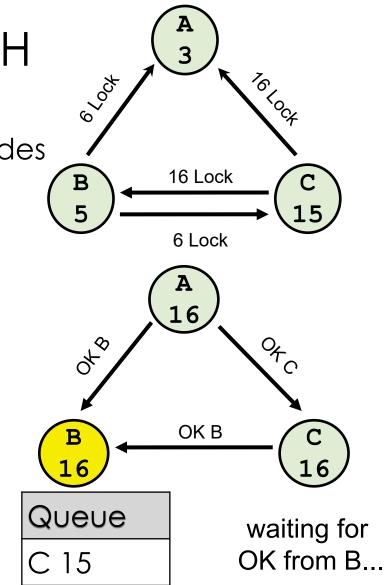

# DISTRIBUTED APPROACH

Use Lamport Clocks to order lock requests across nodes

- Send Lock message with ++clock
  - Wait for OKs from all nodes
- When receiving Lock msg:
  - Update clock following Lamport's rules
  - Send OK if not interested
  - If I want the lock:
    - Send OK if request's clock is smaller than own
    - Else, put request in queue
- When done with a lock:
  - Send OK to anybody in queue

### COMPARISON

- Messages per lock acquire and release
  - Centralized:
  - Distributed:
- Delay before entry
  - Centralized:
  - Distributed:
- Problems
  - Centralized:
  - Distributed:

### COMPARISON

- Messages per lock acquire and release
  - Centralized: 2+1=3
  - Distributed: 2(n-1)
- Delay before entry
  - Centralized: 2
  - Distributed: 2(n-1) in parallel
- Problems
  - Centralized: Coordinator crashes
  - Distributed: anybody crashes

Is the distributed approach better in any way?

### DISTRIBUTED SYSTEMS ARE HARD

- Going from centralized to distributed can be..
- Slower
  - If everyone needs to do more work
- More error prone
  - 10 nodes are 10x more likely to have a failure than one
- Much more complicated
  - If you need a complex protocol
  - If nodes need to know about all others

Often we need more than just a way to lock a resource!

#### What is the meaning of Consensus

- Consensus is defined by Merriam-Webster as,
  - general agreement,
  - group solidarity of belief or sentiment.

# WHY CONSENSUS?

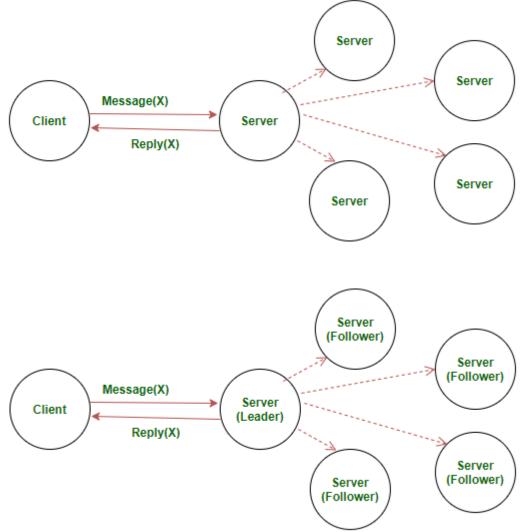

When you sent a request to a server it answers you easily

- If server fails, there is no backup
- If the number of requests increase dramatically the server won't be able to respond

# WHY CONSENSUS ?

- Symmetric: Any of the multiple servers can respond to the client and all the other servers are supposed to sync up with the server that responded to the client's request, and
- Asymmetric: Only the elected leader server can respond to the client. All other servers then sync up with the leader server.

# WHY CONSENSUS?

While this creates a system that is devoid of corruption from a single source, it still creates a major problem.

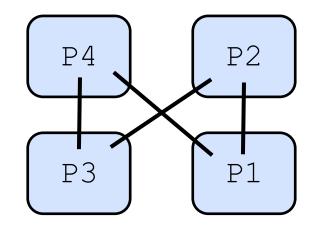

- How are any decisions made?
- How does anything get done?

# CONSENSUS OBJECTIVES

- Therefore, objectives of a consensus mechanism are:
  - Agreement seeking: A consensus mechanism should bring about as much agreement from the group as possible.
  - **Collaborative**: All the participants should aim to work together to achieve a result that puts the best interest of the group first.
  - Cooperative: All the participants shouldn't put their own interests first and work as a team more than individuals.
  - **Egalitarian**: A group trying to achieve consensus should be as egalitarian as possible. What this basically means that each and every vote has equal weight. One person's vote can't be more important than another's.
  - Inclusive: As many people as possible should be involved in the consensus process. It shouldn't be like normal voting where people don't really feel like voting because they believe that their vote won't have any weight in the long run.
  - **Participatory**: The consensus mechanism should be such that everyone should actively participate in the the overall process.

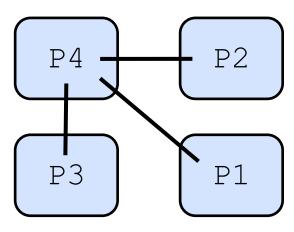

### DISTRIBUTED ARCHITECTURES

 Purely distributed / decentralized architectures are difficult to run correctly and efficiently (decentralized locking was pretty bad!)

**Decentralized** 

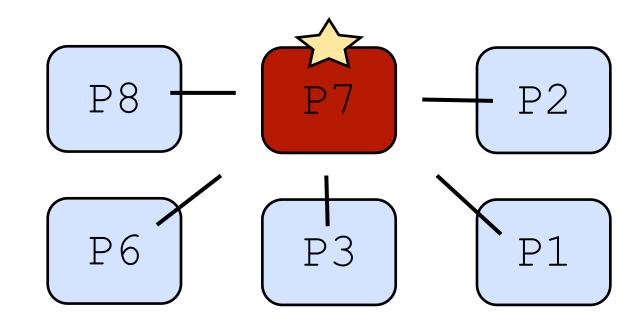

Can we mix the two?

Centralized

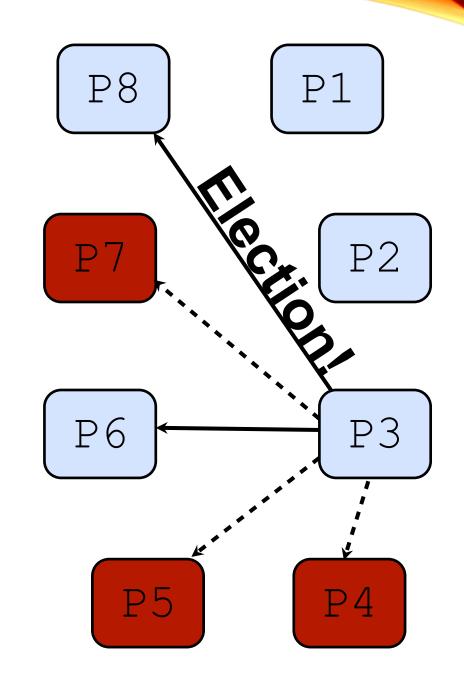

### ELECTIONS

- Appoint a central coordinator
  - But allow them to be replaced in a safe, distributed way
- Must be able to handle simultaneous elections
  - Reach a consistent result
- Who should win?

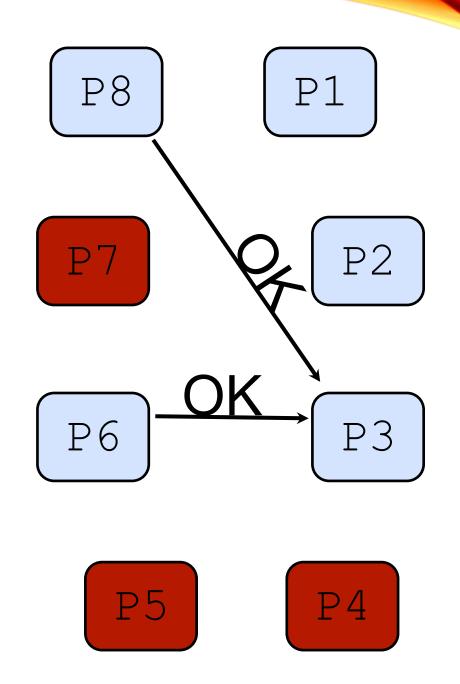

# BULLY ALGORITHM

- The biggest (ID) wins
- Any process P can initiate an election
- P sends Election messages to all process with higher lds and awaits OK messages
- If it receives an OK, it drops out and waits for an I won
- If a process receives an Election msg, it returns an OK...

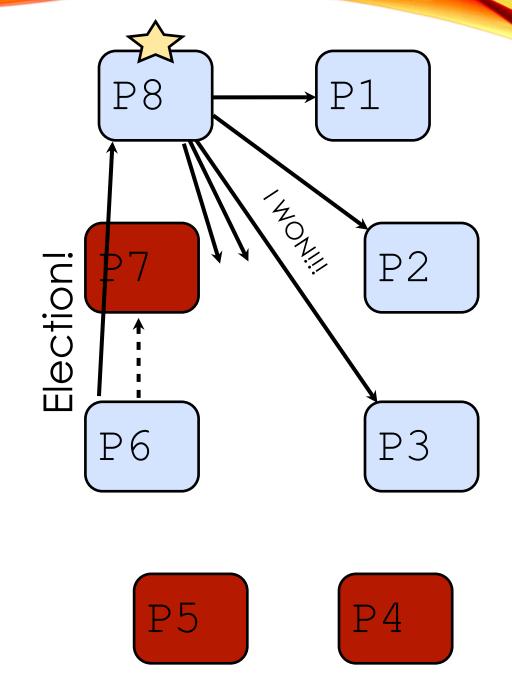

# BULLY ALGORITHM

- The biggest (ID) wins
- Any process P can initiate an election
- P sends Election messages to all process with higher lds and awaits OK messages
- If it receives an OK, it drops out and waits for an I won
- If a process receives an **Election** msg, it returns an **OK**...

# BULLY ALGORITHM

- The biggest (ID) wins
- Any process P can initiate an election
- P sends Election messages to all process with higher lds and awaits OK messages
- If it receives an OK, it drops out and waits for an I won
- If a process receives an Election msg, it returns an OK and starts another election
- If no OK messages, P becomes leader and sends I won to all process with lower Ids
- If a process receives a I won, it treats sender as the leader

# RING ALGORITHM

P8

P1

Any other ideas?

P7

P2

P6

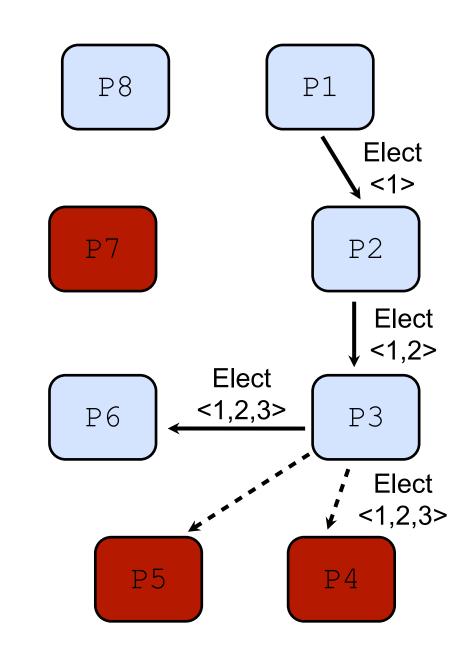

Р3

P5

P4

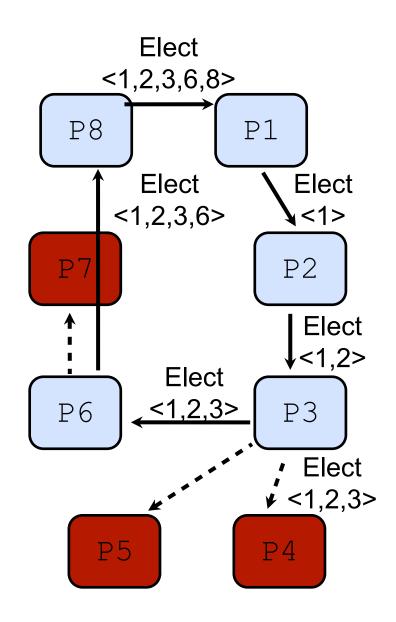

### RING ALGORITHM

- Initiator sends an Election message around the ring
- Add your ID to the message
- When Initiator receives message again, it announces the winner
- What happens if multiple elections occur at the same time?

### RING ALGORITHM

- Initiator sends an Election message around the ring
- Add your ID to the message
- When Initiator receives message again, it announces the winner
- What happens if multiple elections occur at the same time?

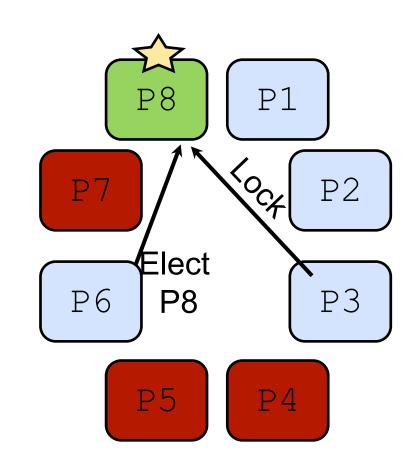

### COMPARISON

- Number of messages sent to elect a leader:
- Bully Algorithm
  - Worst case: lowest ID node initiates election
    - Triggers n-1 elections at every other node = O(n^2) messages
  - Best case: Immediate election after n-2 messages
- Ring Algorithm
  - Always 2(n-1) messages
  - Around the ring, then notify all

#### ELECTIONS + CENTRALIZED LOCKING

- Elect a leader
- Let them make all the decisions about locks
- What kinds of failures can we handle?
  - Leader/non-leader?
  - Locked/unlocked?
  - During election?

This can be the basis for **consensus**-based distributed systems!

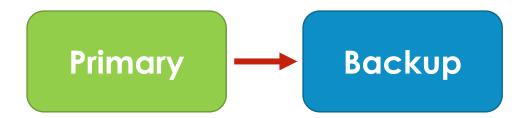

# CHUBBY: GOOGLE'S LOCK SERVICE

- Google services are composed of many thousands of nodes
- Need a way to coordinate data and access to shared resources!
  - Used by Google File System, BigTable, etc.
- Chubby: lock service for loosely coupled distributed systems
  - Focuses on availability and reliability (not performance)
  - Scales to ~10,000 servers per Chubby Cell
- See paper at OSDI 2006 by Mike Burrows for full details!

# STATE MACHINE REPLICATION (SMR)

- We can think of an application as a state machine
  - A program is just data that is updated based on operations -> state
- Consensus means that all distributed nodes should be in the same state!
  - If a node fails, it should not disrupt the system
  - When a node recovers it should be able to "catch up"

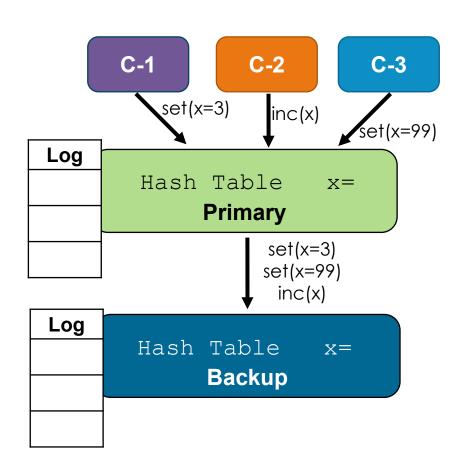

### DISTRIBUTED VIDEO EDITING SMR

- Sometimes data is big!
- Replicate the operation to be performed, not the data!
- Treat like a state machine
  - Incoming requests just perform some operation on that data
  - If all replicas perform same operations, they will end in the same state
- If Primary fails, switch to Backup

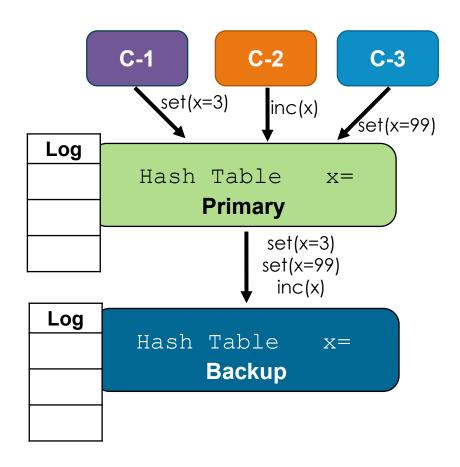

### HASH TABLE SMR

- SMR creates a replicated log of actions to be performed
  - E.g., updates to the value stored by a key
- Primary orders incoming requests to form the log
- Actions must be deterministic
- We can keep adding more backup replicas to improve fault tolerance

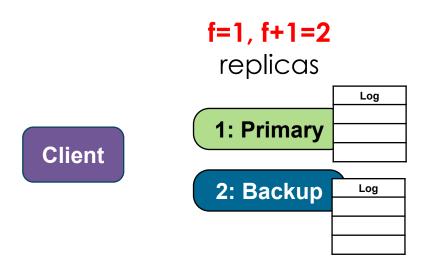

# SMR FAILURES?

- What to do on a failure?
- How many failures can we handle?

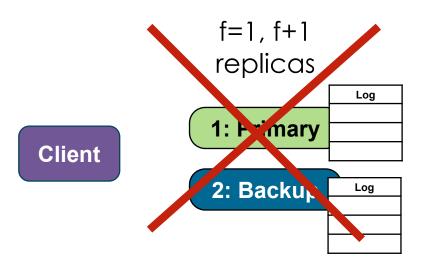

- F = number of nodes which can crash at one time
- # of nodes needed must depend on f!

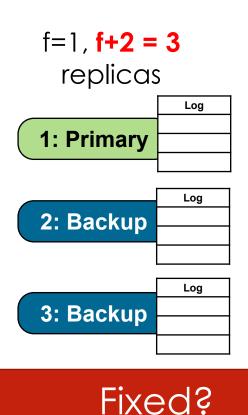

What failure scenarios can happen?

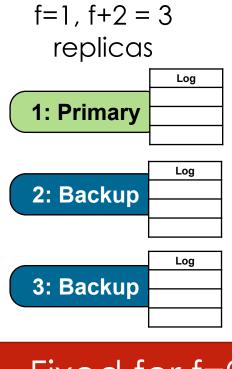

- F = number of nodes which can crash at one time
- # of nodes needed must depend on f!

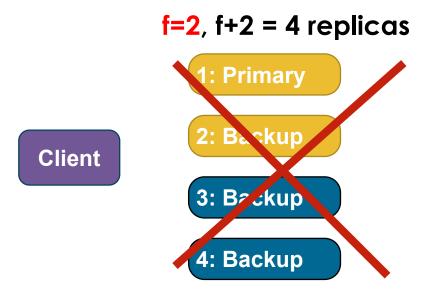

Can't resync state if failure "flip flops" between nodes!

- F = number of nodes which can crash at one time
- # of nodes needed must depend on f!

- F = number of nodes which can crash at one time
- # of nodes needed must depend on f!

Can't resync state if failure "flip flops" between **2** nodes!

f=1, f+2 = 3
replicas

1: Primary

2: Backup

Log

Log

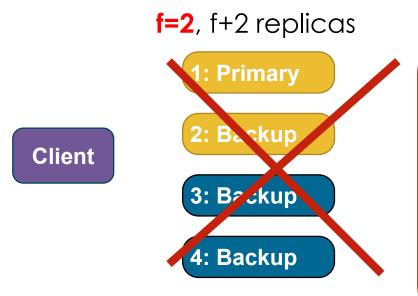

Log

Log

Log

Fixed for f=2? No!

- F = number of nodes which can crash at one time
- # of nodes needed must depend on f!

Can't resync state if failure "flip flops" between **2** nodes!

Use **2f+1**replicas!
Insight: Always
need a **majority**of nodes to stay
alive!

f=2, 2f+1 = 5 replicas

**Primary** 

**Backup** 

Backup

**Backup** 

Backup

Prof. Tim Wood & Prof. Roozbeh Haghnazar

#### STATE MACHINE REPLICATION OVERVIEW

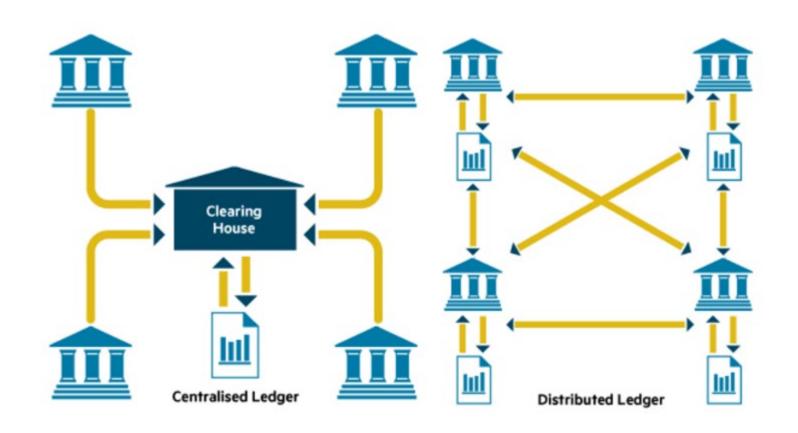

- Provides a generic fault tolerance mechanism
  - Application just needs to have well defined operations and a way to avoid nondeterminism
- Primary orders requests into log
- Backups execute log in order
- Log allows out of date replicas to recover
- Need 2f+1 replicas to tolerate f failures
- But how do we pick who should be primary...?
  - Use an election algorithm!

**Optional**: Example for your project

# CASE STUDY

- Two important challenges in BlockChain
  - How are any decisions made?
  - How does anything get done?

# DISTRIBUTED LEDGER TECH

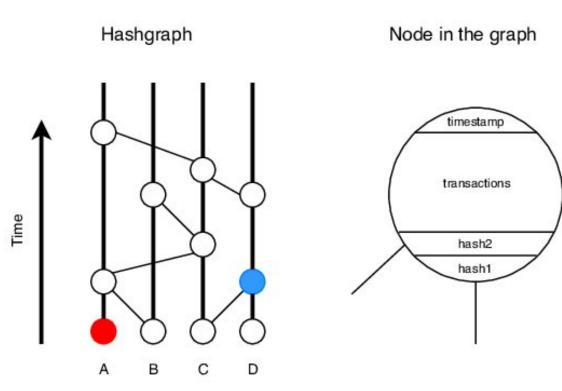

### DIFFERENT TYPES OF DLT

- Blockchain
- Hashgraph
- DAG
- Holochain
- Tangle
- Radix (Tempo)
- <a href="https://www.researchgate.net/publication/328475892">https://www.researchgate.net/publication/328475892</a> A Review of Distributed Ledger Technologies/figures?lo=1

# HASHGRAPH

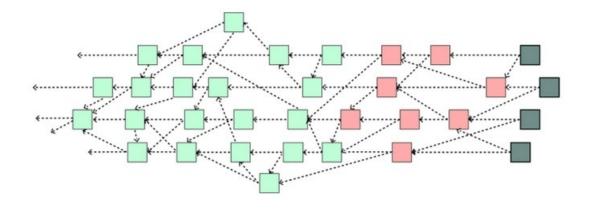

- It's so fast 250000 transaction per second (Scalability characteristics in Distributed Systems)
- Being Time-Based and using Gossip protocol for consensus reduces the process and math complexity.
- Time-based increases the justice. Each transaction who obtained 2/3 of the votes has the most priority and it can be a weakness
- In the level of security it is evaluating in the banking system level and it means it is a **Byzantine Fault Tolerance** system.
- Controlled Network (Consensus is easier)

Hashgraph Data Structure

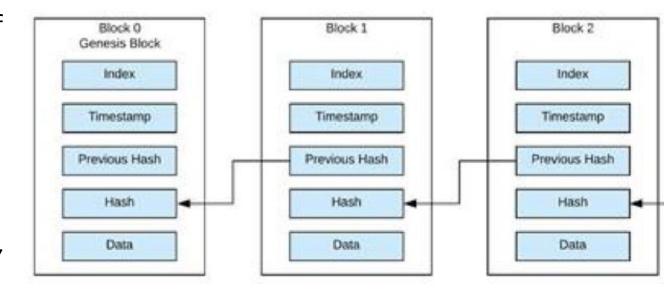

# TANGLE (IOTA)

- IOTA is an open-source distributed ledger and cryptocurrency designed for the Internet of things.
- Uses DAG to store transactions on its ledger, motivated by a potentially higher scalability over blockchain based distributed ledgers for nano-Transactions between IOT devices.
- There are categories of participants,
  - Transaction creators
  - Transaction verifiers

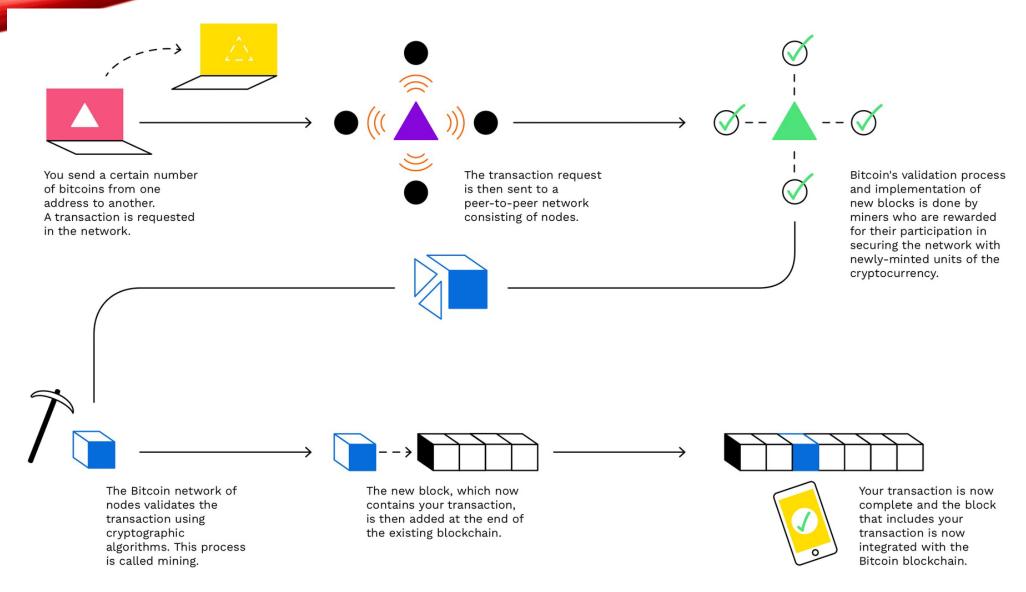

# BLOCKCHAIN

- Unofficial definition: A blockchain is an unchangeable and sequence of records and transactions which is called **BLOCK**
- The blocks connects to each other with Hash Codes
- Each block contains an index, time stamp, list of transactions, evidence, and last block hash (which guarantees the unchangeability of the chain)

# HOW DOES IT WORK? EX. BITCOIN

# Consensus in BlockChain

- A consensus mechanism enables the blockchain network to attain reliability and build a level of trust between different nodes, while ensuring security in the environment.
  - Proof of Work (PoW)
  - Proof of Stake (PoS)
  - Delegated Proof of Stake (DPoS)
  - Leased Proof of Stake (LPoS)
  - Direct Acyclic Graph (DAG)
  - Byzantine Fault Tolerance (BFT)
  - Practical Byzantine Fault Tolerance (PBFT)
  - Delegated Byzantine Fault Tolerance (DBFT)
  - Proof of Capacity (PoC)
  - Etc.
